**Abstract:** This study (research) was carried out in the city of Mitrovica, which is situated in Kosovo north with geographical coordinates 42 degrees and 53 min in Kosovo north and 20 degrees and 52 min in the east. More concretely, the monitoring covers the area in north-east part of Mitrovica, where the scope of monitoring is 7 km of air space. Total number of monitoring points is 9, which cover the urban area with a higher density of population. From the use of Lead and Zinc Mine in Stan -Tërg and activities carried out by chemical industries in the area in the past, a serious problem was caused in this part of Mitrovica in environment degradation with the created dust depositions dumps from the remains of chemical-technological processes of the mine in Zvecan and other industrial activities. These depositions are a permanent source of air pollution, which was suspended in air at any time. Exposure to certain types of settled dust and it's associated contaminant load can be detrimental to human health. In this study, we are focused on researching air pollution by dust deposition during years 2006 and 2007, and dust-fall ranged from 79.361 to 2303.10 mg/m<sup>2</sup>day according to our study, where we can conclude that there is an enormous excess in water quality according to WHO standards. We did a comparison of air pollution for this period and we monitored the meteorological conditions in the spread of dust from the created depositions from the mine use and industrial activities.

Keywords: spatial distribution of deposition (precipitate), deposited dust, meteorological conditions

# **Spatial Distribution of Deposited Dust**

Depositions created from Trepça mine use and chemical-technological processes of battery factory, Zinc electrolysis and phosphoric fertilizers' factory pose a permanent source of air pollution. Considering that these depositions are not treated, and considering orograph of Mitrovica city, orograph of deposition locations, insulation process, radiation, wind speed and wind direction, these depositions are constantly under the influence of wind speed and direction of atmospheric conditions which affect the distribution of granules according to Table 1&2 and Figure 1, which cause the air pollution with different kinds of granules.

Orograph of Mitrovica territory and the area (spatial area) that we covered through our study has favorable conditions for dust distribution from the above-mentioned dust depositions. In our study we found that there was a higher concentration of dust distribution in the monitoring points in *School "Bedri Gjina"*, *Trepca Industrial Park*, *OSCE*, and *Tobacco Factory Bair*.

# **Material and Methods**

Dust deposition sampling was conducted using a Frisbee Dust Deposit (FDD) gauge, which was recently developed by the Stockholm Environment Institute and according to Ref.47should have significantly higher collection efficiencies during high winds than both the British Standard deposition gauge and the ISO gauge.

Upward facing polythene cylindrical container with the top edge beveled at 45°. Top of the cylinder is approximately 1.7m above the ground. The sampling programmed should be long duration, e.g. 1 year, with individual exposure periods of up to 1 month.

After sampling the collector is removed to the laboratory and the insoluble deposited matter is separated by vacuum filtration and gravimetrically determined after drying. Deposition is expressed as  $mg/m^2/day$ .Limited collection efficiency, dependent on wind speed.

### **Results and discussion**

Based on the two year monitoring of dust depositions, we did a permanent monitoring in 9 monitoring points in south-east part of Mitrovica, where these monitoring points covered

the area with a higher density of population. We usually took samples from the school locations (See Table 4).

From the monitored data, our results show a variation of obtained data through lab results where in School "Bedri Gjina", Trepca Industrial Park, OSCE, Tobacco Factory-Bair monitoring points, we have extreme values of excess according to points in Table 4 & 5, where the maximum concentration was 5560.8 mg/m2/day at OSCE sample location in April 2007, while minimum value was 40.31 mg/m2/day at Smërkovnica sample location, during August 2007.

In the following tables, we have presented the concentration values of deposited dust in 9 monitoring points. These values are mainly linked to the climatologically conditions during 2006 and 2007, where there are extreme values of fluctuations of all elements and meteorological phenomena.

Dominating factors in variation of values from 2006 to 2007 included climatological factors, where 2006 was characterized by a high amount of precipitation, while 2007 was the year with highest temperatures in past 50 years, where gradient of temperature was unstable. Also the baric field had huge fluctuation, and these two meteorological elements create the wind which in Mitrovica and region has up to 32 directions according to wind rose, and with a very high intensity which caused distribution of granules. Therefore, Mitrovica city and its surrounding have a high level of pollution by the amount of settled dust which is very dangerous for the health of the population. Considering the origin of the dust which comes from mine depositions created in decades and which were never treated. It is in the interest of population health that these depositions are treated professionally in order that atmospheric processes don't have an impact on suspense of granules on the air from the depositions, which are a composing substance of aerosols which are inhalating granules that directly enter organisms and have very

dangerous consequences. From the annual average values that we obtained in 2006 and 2007 we found that in the same points there were excesses of recommended maximum values according to WHO, which are presented in the following diagram

Table 6. Total deposited dust in 2006 year

# Conclusion

- From two year monitoring of air quality by the dust deposition polluter, from the obtained values we can conclude that Mitrovica city, and its south-east part in particular has a high level of pollution with the above-mentioned granules, where the maximum value reaches 5560.8mg/m<sup>2</sup>/day, which exceeds WHO recommended values for 20
- From the obtained data in our study, it can be seen that in the area of 1m<sup>2</sup>, the level of pollution is 542.3 mg per day, where the population of the region is exposed to this pollution during the entire day.
- Building of new factories poses a special problem in the increase of the pollution level, since both natural resources and air quality in the region are contaminated by technological processes which pose a hazard to the human health.
- It is required a treatment of depositions according to EU standards for these kind of depositions, where elements and meteorological phenomena could not have an impact in air pollution by the dust distributed from dust deposition of mineral and industrial remains.
- Surface water and groundwater should not be in contact with the discharged water from the drainage of the depositions, since the water from the drainage is discharged in Ibri and Sitnica rivers, and thus cause pollution in both water and soil.
